On generalized Lotka-Volterra lattices

A. Dimakis¹ and F. Müller-Hoissen²

Abstract

Generalized matrix Lotka-Volterra lattice equations are obtained in a systematic way from a "master equation" possessing a bicomplex formulation.

1 Introduction

A bicomplex is an \mathbb{N}_0 -graded linear space (over \mathbb{R}) $\mathcal{M} = \bigoplus_{s \geq 0} \mathcal{M}^s$ together with two linear maps $\mathcal{D}, D : \mathcal{M}^s \to \mathcal{M}^{s+1}$ satisfying $(\mathcal{D} - \lambda D)^2 = 0$ for all $\lambda \in \mathbb{R}$. If this holds as a consequence of a certain (partial differential or difference) equation, we speak of a bicomplex formulation for this equation [1, 2]. It may be regarded as a special case of a parameter-dependent zero curvature condition. In this work we derive generalized Lotka-Volterra (LV) lattices (see [3, 4, 5, 6, 7], for example) from a "master equation" with a bicomplex formulation. Some consequences of the latter (conservation laws [1], Bäcklund transformations [2]) are briefly discussed. We choose the bicomplex space as $\mathcal{M} = \mathcal{M}^0 \otimes \Lambda$ where $\Lambda = \bigoplus_{s=0}^2 \Lambda^s$ is the exterior algebra of a 2-dimensional vector space with a basis ξ, η of Λ^1 . It is sufficient to define bicomplex maps on \mathcal{M}^0 , since by linearity and action on the coefficients of monomials in ξ, η they extend to the whole of \mathcal{M} (cf [1, 2]). On \mathcal{M}^0 we define

$$\delta z = (z - S^{q-p}z) \, \xi + \dot{z} \, \eta \,, \qquad dz = (S^q z - z) \, \xi + (S^p z - z) \, \eta$$
 (1)

where $\dot{z}=dz/dt$, S is an invertible linear operator on \mathcal{M}^0 with $\dot{S}=0$, and $p,q\in\mathbb{Z}$. The bicomplex equations for $(\mathcal{M},\delta,\mathrm{d})$ are then identically satisfied. In the following, the maps δ and d will be "dressed", resulting in nontrivial bicomplexes.

2 A class of generalized Lotka-Volterra equations and its properties

2.1 A bicomplex for generalized LV equations

Let us replace d by a map D which acts as follows on \mathcal{M}^0 ,

$$Dz = (Q S^q z - z) \xi + (P S^p z - z) \eta$$
(2)

where Q and P are linear operators on \mathcal{M}^0 . Then (\mathcal{M}, δ, D) is a bicomplex iff

$$QS^q PS^p = PS^p QS^q, \qquad \dot{Q}S^q = PS^q - S^{q-p} PS^p. \tag{3}$$

Choosing \mathcal{M}^0 as the set of \mathbb{C}^m -valued functions (on an infinite lattice) $z_n(t)$, $n \in \mathbb{Z}$, and $(Sz)_n = z_{n+1}$, $(Qz)_n = Q_n z_n$, $(Pz)_n = P_n z_n$, (3) becomes

$$Q_n P_{n+q} = P_n Q_{n+p} , \qquad \dot{Q}_n = P_n - P_{n+q-p} .$$
 (4)

The ansatz

$$Q_n = g_n^{-1} g_{n+q}, \qquad P_n = g_n^{-1} g_{n+p} \tag{5}$$

with invertible matrices g_n now solves the first equation and turns the second into

$$(g_n^{-1}g_{n+q})^{\bullet} = g_n^{-1}g_{n+p} - g_{n+q-p}^{-1}g_{n+q}.$$
(6)

In the following we exclude the trivial cases where p=0 or q=0. If p and q are not coprime, let s denote their greatest common divisor, so that p=sp' and q=sq' where p',q' are coprime. The above equation then decomposes into independent equivalent equations on s sublattices. Therefore we restrict q and p to be coprime. Since $\{p,q,n,g_n\} \mapsto \{-p,-q,-n,g_{-n}\}$ is a symmetry of (6), it is sufficient to consider q>0. Generalized LV equations are now obtained as follows. Introducing

$$V_n := g_n^{-1} g_{n+1} \tag{7}$$

equation (6) takes the form

$$(V_n \cdots V_{n+q-1})^{\bullet} = \begin{cases} V_n \cdots V_{n+p-1} - V_{n+q-p} \cdots V_{n+q-1} & \text{if } p > 0 \\ V_{n-1}^{-1} \cdots V_{n+p}^{-1} - V_{n+q-p-1}^{-1} \cdots V_{n+q}^{-1} & \text{if } p < 0 \end{cases}$$
(8)

In the case where V_n are scalars, we write a_n instead of V_n and the last two equations turn out to be the "extended Lotka-Volterra equations" studied in [3, 6]. For q = 1, they reduce to $\dot{a}_n = a_n (a_{n+1} \cdots a_{n+p-1} - a_{n-p+1} \cdots a_{n-1})$ and $\dot{a}_n = a_{n-1}^{-1} \cdots a_{n+p}^{-1} - a_{n+1}^{-1} \cdots a_{n-p}^{-1}$, respectively, which have been explored in particular in [5, 7].

Remark. In case of a finite open lattice of N points, choose $S = \sum_{i=1}^{N-1} E_{i,i+1}$ where $E_{i,j}$ are the elementary matrices with a 1 at the ith row and jth column and otherwise zeros, and define S^{-1} as the transpose of S. Since $[S, S^T] \neq 0$, (1) does not yield a bicomplex. But after dressing, a bicomplex (\mathcal{M}, δ, D) for the finite open LV equation is obtained. For a periodic lattice choose $S = \sum_{i=1}^{N-1} E_{i,i+1} + E_{N,1}$.

2.2 The bicomplex linear system and conservation laws

The bicomplex linear system [1] for the bicomplex introduced above is $\delta \chi = \lambda D \chi$ with an $m \times m$ matrix field χ . The integrability condition $\delta D \chi = 0$ leads to

$$(Q_n \chi_{n+q} - \chi_n)^{\cdot} = P_n \chi_{n+p} - \chi_n - (P_{n+q-p} \chi_{n+q} - \chi_{n+q-p})$$
(9)

which has the form of a conservation law. As a consequence,

$$Q_{i} = \lambda \sum_{k=-\infty}^{+\infty} (Q_{i+k(q-p)} \chi_{i+q+k(q-p)} - \chi_{i+k(q-p)})$$
(10)

where i = 0, 1, ..., |q - p| - 1, are conserved charges, i.e. $\dot{Q}_i = 0$. The linear system reads $\chi_n - \chi_{n+q-p} = \lambda (Q_n \chi_{n+q} - \chi_n)$, $\dot{\chi}_n = \lambda (P_n \chi_{n+p} - \chi_n)$. These equations can be solved iteratively with a power series expansion $\chi = \sum_{r=0}^{\infty} \lambda^r \chi^{(r)}$. Starting with $\chi^{(0)} = I$, the unit matrix, we find the first set of conserved quantities

$$Q_i^{(1)} = \sum_{k=-\infty}^{+\infty} (Q_{i+k(q-p)} - I).$$
(11)

Solving the linear system for $\chi^{(1)}$ leads to $\chi_n^{(1)} - \chi_{n+q-p}^{(1)} = Q_n - I$ and thus

$$\chi_n^{(1)} = \sum_{j=1}^{\infty} (I - Q_{n-j(q-p)}) \tag{12}$$

with the help of which one obtains the second set of conserved charges,

$$Q_i^{(2)} = \sum_{k=-\infty}^{+\infty} \left(Q_{i+k(q-p)} \sum_{j=1}^{\infty} (I - Q_{i+q+(k-j)(q-p)}) - \sum_{j=1}^{\infty} (I - Q_{i+(k-j)(q-p)}) \right)$$
(13)

and so forth. Expressing Q_n in terms of V_n via (5) and (7), conserved charges are obtained for the LV equations (8).

2.3 Bäcklund transformations

A "Darboux-Bäcklund transformation" (DBT) of a bicomplex leads to a Bäcklund transformation (BT) of the associated equation [2]. In order to determine a (primary) auto-DBT of the bicomplex associated with (6), one has to find an operator R_{21} on \mathcal{M}^0 which solves the equations $[\delta, R_{21}] = D_2 - D_1$ and $D_2 R_{21} = R_{21} D_1$ where D_1, D_2 are the bicomplex map D depending on solutions g_1 and g_2 of (6), respectively. With $R_{21} = r S^p$, where r is a function, this leads to

$$r_n - r_{n+q-p} = Q_{2,n} - Q_{1,n}, \qquad \dot{r}_n = P_{2,n} - P_{1,n}$$
 (14)

$$Q_{2,n} r_{n+q} = r_n Q_{1,n+p}, \qquad P_{2,n} r_{n+p} = r_n P_{1,n+p}.$$
 (15)

Using (5), (15) becomes $A_{n+q} = A_n = A_{n+p}$ where $A_n = g_{2,n} r_n g_{1,n+p}^{-1}$. Since p, q are relatively prime, according to the Euclidean algorithm there are integers k, l such that kq - lp = 1. Hence $A_{n+1} = A_{n+1+lp} = A_{n+kq} = A_n$ and thus

$$r_n = g_{2,n}^{-1} A(t) g_{1,n+p}$$
(16)

with an arbitrary matrix A depending on t only. (14) now produces a BT:

$$g_{2,n}^{-1} A g_{1,n+p} - g_{2,n+q-p}^{-1} A g_{1,n+q} = g_{2,n}^{-1} g_{2,n+q} - g_{1,n}^{-1} g_{1,n+q}$$
(17)

$$(g_{2,n}^{-1} A g_{1,n+p})^{\bullet} = g_{2,n}^{-1} g_{2,n+p} - g_{1,n}^{-1} g_{1,n+p}.$$
 (18)

In the case under consideration, the "permutability theorem" takes the form $R_{31} + R_{10} = R_{32} + R_{20}$ (see [2] for details). This leads to the superposition formula

$$g_{3,n} = (A_1 g_{2,n+p} - A_2 g_{1,n+p}) g_{0,n+p}^{-1} (g_{1,n}^{-1} A_1 - g_{2,n}^{-1} A_2)^{-1}.$$
(19)

In the scalar case, the above BT can be transformed into Hirota's bilinear form [2]. BTs of the scalar generalized LV equations have been derived previously in [6].

2.4 Another class of generalized LV equations

Instead of d, now we dress the operator δ of the trivial bicomplex (\mathcal{M}, d, δ) :

$$\mathcal{D}z = (z - LS^{q-p}z)\xi + (\dot{z} - Mz)\eta \tag{20}$$

with linear operators L and M. The bicomplex conditions for $(\mathcal{M}, \mathcal{D}, d)$ are

$$S^{q}M - MS^{q} = S^{p}LS^{q-p} - LS^{q}, \qquad \dot{L}S^{q-p} = MLS^{q-p} - LS^{q-p}M.$$
 (21)

Choosing $(Sz)_n = z_{n+1}$, $(Lz)_n = L_n z_n$ and $(Mz)_n = M_n z_n$, this takes the form

$$M_{n+q} - M_n = L_{n+p} - L_n , \quad \dot{L}_n = M_n L_n - L_n M_{n+q-p} .$$
 (22)

Remark. $L_n = g_{n+p} g_{n+q}^{-1}$ and $M_n = \dot{g}_{n+p} g_{n+p}^{-1}$ solve (22b) and (22a) becomes (6), so that the bicomplex conditions for (\mathcal{M}, δ, D) and $(\mathcal{M}, \mathcal{D}, d)$ coincide. Then $\mathcal{D} = g \delta g^{-1}$ and $d = g D g^{-1}$, so that the two bicomplexes are gauge equivalent.

The first equation of (22) can be solved by setting

$$M_n = G_{n+p} - G_n$$
, $L_n = G_{n+q} - G_n$ (23)

with matrices $G_n(t)$. The second equation then reads

$$(G_{n+q} - G_n)^{\bullet} = (G_{n+p} - G_n)(G_{n+q} - G_n) - (G_{n+q} - G_n)(G_{n+q} - G_{n+q-p}). \tag{24}$$

Again we should restrict p, q to be coprime and different from zero. Since the map $\{p, q, n, G_n\} \mapsto \{-p, -q, -n, G_{-n}\}$ is a symmetry of (24), it is sufficient to consider q > 0. Moreover, the substitution p = q - p' turns (24) with p < 0 into the same equation where G_n is replaced by G_n^T and p replaced by p'. Since p' > q, we thus only need to consider p, q > 0. Introducing $W_n := G_{n+1} - G_n$ we obtain

$$\frac{d}{dt} \sum_{i=0}^{q-1} W_{n+i} = \left(\sum_{j=0}^{p-1} W_{n+j}\right) \sum_{i=0}^{q-1} W_{n+i} - \left(\sum_{i=0}^{q-1} W_{n+i}\right) \sum_{j=1-q}^{p-q} W_{n-j}.$$
 (25)

The scalar case with q = 1 and p > 1 has been studied by various authors [4, 5, 7].

3 Discrete time generalized Lotka-Volterra equations

A. In order to obtain discrete time counterparts (see [7, 8]) of the generalized LV equations in section 2, we simply have to replace the trivial bicomplex (\mathcal{M}, δ, d) introduced above by a time-discretized version:

$$\delta z = (z - TS^{q-p}z)\,\xi + h^{-1}\,(Tz - z)\,\eta\,,\qquad dz = (S^q z - z)\,\xi + (S^p z - z)\,\eta\tag{26}$$

where \mathcal{M}^0 is now chosen as the set of \mathbb{C}^m -valued functions $z_n(t)$ depending on two discrete variables $n \in \mathbb{Z}$, $t \in h\mathbb{Z}$ with $h \in \mathbb{R} \setminus \{0\}$. The operators S and T act on \mathcal{M}^0 according to $(Sz)_n(t) = z_{n+1}(t)$ and $(Tz)_n(t) = z_n(t+h) =: \tilde{z}_n(t)$. Next we dress d as in (2) with $(Qz)_n = Q_n z_n$ and $(Pz)_n = P_n z_n$. The resulting bicomplex equations are

$$Q_n P_{n+q} = P_n Q_{n+p}, \qquad \tilde{Q}_n - Q_n = h (P_n - \tilde{P}_{n+q-p}).$$
 (27)

The ansatz (5) solves the first equation and turns the second into

$$\tilde{g}_n^{-1}\,\tilde{g}_{n+q} - g_n^{-1}\,g_{n+q} = h\left(g_n^{-1}\,g_{n+p} - \tilde{g}_{n+q-p}^{-1}\,\tilde{g}_{n+q}\right). \tag{28}$$

Again, we may restrict to coprime p, q and q > 0. Using (7), we obtain

$$(I + h \, \tilde{V}_{n+q-p} \cdots \tilde{V}_{n-1}) \, \tilde{V}_n \cdots \tilde{V}_{n+q-1} = V_n \cdots V_{n+q-1} \, (I + h \, V_{n+q} \cdots V_{n+p-1})$$
 (29)

if p > q. In the scalar case with q = 1 we recover equation (3.5) in [8]:

$$\tilde{a}_n \left(1 + h \prod_{i=1}^{p-1} \tilde{a}_{n-i} \right) = a_n \left(1 + h \prod_{i=1}^{p-1} a_{n+i} \right).$$
 (30)

If 0 , (28) leads to

$$(\tilde{V}_{n} \cdots \tilde{V}_{n+q-p-1} + h I) \tilde{V}_{n+q-p} \cdots \tilde{V}_{n+q-1} = V_{n} \cdots V_{n+p-1} (V_{n+p} \cdots V_{n+q-1} + h I)$$
(31)

which can be mapped to (29) via a redefinition $T \mapsto TS^{p-q}$ (so that $\tilde{V}_n(t) = V_{n+p-q}(t+h)$) and a subsequent replacement $(h, p, q) \mapsto (h^{-1}, q, p)$. Finally, if p = -r < 0, equation (28) takes the form

$$\tilde{g}_n^{-1}\,\tilde{g}_{n+q} - g_n^{-1}\,g_{n+q} = h\left[(g_{n-r}^{-1}\,g_n)^{-1} - (\tilde{g}_{n+q}^{-1}\,\tilde{g}_{n+q+r})^{-1} \right] \tag{32}$$

which in terms of V_n reads

$$(I + h\tilde{V}_{n+q+r-1}^{-1} \cdots \tilde{V}_n^{-1})\tilde{V}_n \cdots \tilde{V}_{n+q-1} = V_n \cdots V_{n+q-1} (I + hV_{n+q-1}^{-1} \cdots V_{n-r}^{-1}).$$
 (33)

In the scalar case with q = 1 this reduces to

$$\tilde{a}_n \left(1 + h \prod_{i=0}^r \tilde{a}_{n+i}^{-1} \right) = a_n \left(1 + h \prod_{i=0}^r a_{n-i}^{-1} \right)$$
(34)

and with a change of variable $v_n = a_{-n}$ we recover equation (3.9) in [8].

B. Let us now consider a dressing of δ (while leaving d unchanged):

$$\mathcal{D}z = (z - LTS^{q-p}z)\xi + h^{-1}(MTz - z)\eta$$
(35)

with $(Lz)_n = L_n z_n$ and $(Mz)_n = M_n z_n$. $(\mathcal{M}, \mathcal{D}, d)$ is a bicomplex if and only if

$$L_n \tilde{M}_{n+q-n} = M_n \tilde{L}_n, \quad L_n - L_{n+n} = h^{-1} (M_{n+q} - M_n).$$
 (36)

Remark. Writing $L_n(t) = g_{n+p}(t-h) g_{n+q}(t)^{-1}$ and $M_n(t) = g_{n+p}(t-h) \tilde{g}_{n+p}(t)^{-1}$, the two bicomplexes (\mathcal{M}, δ, D) and $(\mathcal{M}, \mathcal{D}, d)$ are gauge equivalent.

The ansatz $L_n = G_n - G_{n+q}$, $M_n = I + h(G_{n+p} - G_n)$ solves (36b) and yields the correct $h \to 0$ limit for \mathcal{D} . Now (36a) becomes

$$(G_{n+q} - G_n) [I + h (\tilde{G}_{n+q} - \tilde{G}_{n+q-p})] = [I + h (G_{n+p} - G_n)] (\tilde{G}_{n+q} - \tilde{G}_n).$$
 (37)

Again, we may assume q > 0. If p > 0, in terms of $W_n = G_{n+1} - G_n$ (37) reads

$$\left(\sum_{i=0}^{q-1} W_{n+i}\right) \left(I + h \sum_{j=1-q}^{p-q} \tilde{W}_{n-j}\right) = \left(I + h \sum_{j=0}^{p-1} W_{n+j}\right) \sum_{i=0}^{q-1} \tilde{W}_{n+i}.$$
(38)

Even for q=1 and $p\geq 1$ and in the scalar case this appears to be a new integrable time-discretization of the corresponding LV equation (which is a special case of (25)). It is different from the discretization (3.1) in [8]. If p<0, (37) is mapped via $(p,q,h,t,G_n)\mapsto (q-p,q,-h,t+h,G_n^T)$ to the above case with positive p.

4 LV equations as reductions of a three-dimensional equation

Another trivial bicomplex (\mathcal{M}, δ, d) is obtained by replacing (26) with

$$\delta z = (z - TK\Lambda^{-1}z)\xi + h^{-1}(Tz - z)\eta, \qquad dz = (Kz - z)\xi + (\Lambda z - z)\eta$$
 (39)

where $(Tz)_{k,l}(t) = z_{k,l}(t+h)$, $(Kz)_{k,l} = z_{k+1,l}$ and $(\Lambda z)_{k,l} = z_{k,l+1}$ are acting on the set \mathcal{M}^0 of \mathbb{C}^m -valued functions $z_{k,l}(t)$ depending on three discrete variables $k,l \in \mathbb{Z}$, $t \in h\mathbb{Z}$. The dressing $Dz = (QKz - z)\xi + (P\Lambda z - z)\eta$ with $Q_{k,l} = g_{k,l}^{-1} g_{k+1,l}$ and $P_{k,l} = g_{k,l}^{-1} g_{k,l+1}$ then leads to a bicomplex (\mathcal{M}, δ, D) associated with

$$\tilde{g}_{k,l}^{-1}\,\tilde{g}_{k+1,l} - g_{k,l}^{-1}\,g_{k+1,l} = h\left(g_{k,l}^{-1}\,g_{k,l+1} - \tilde{g}_{k+1,l-1}^{-1}\,\tilde{g}_{k+1,l}\right). \tag{40}$$

In the scalar case, this equation should be equivalent to the discrete Hirota equation (cf [2], section 4.2.5). If all the fields only depend on n := kq + lp with fixed $p, q \in \mathbb{Z}$, we recover equation (28). The continuous time limit of (40) is

$$(g_{k,l}^{-1}g_{k+1,l})^{\bullet} = g_{k,l}^{-1}g_{k,l+1} - g_{k+1,l-1}^{-1}g_{k+1,l} . \tag{41}$$
